

Differentiating Large-Scale Finite Element Applications with MFEM

Julian Andrej

Usual approach to Automatic Differentiation

- AD is often perceived as a black-box tool
 - Applied at the highest possible level
 - Low implementation barrier
- AD tool has to work through
 - Complicated program structures
 - Non-trivial object types
 - Sometimes even communication layers like MPI
- Infeasible overhead in our applications even for the smallest problems
 - We must balance the implementation effort with AD convenience to ensure the least overhead possible
 - Carefully decide entry points
 - Still provide a clear and concise interface for users
- GPUs make things worse 100x (underestimated guess)

Constrain AD to the quadrature point level ... $\xrightleftharpoons[B^T]{B}$

Finite Element Operator Decomposition

Decompose A into **parallel**, mesh, **finite element**, and **geometry/physics** components

$$A = P^T G^T B^T D B G P$$

Finite Element Operator Decomposition

Decompose **A** into **parallel**, mesh, **finite element**, and **geometry/physics** components

$$\nabla_u A(u; \rho) = P^T G^T B^T \nabla_{\hat{u}} D(\hat{u}, \hat{\rho})$$

Why Enzyme for Automatic Differentiation?

- Production codes are compositions of complicated physics
 - Variety of domain experts work on parts of the code
 - Multiple programming languages
- Material models lead to additional experts that only see and work on specific parts of the code
- Enzyme allows us to still use the complex combination of a libraries which
 - May be written in a different programming language
 - Can't be modified to allow different approaches of AD (e.g., type overloading)
 - User might be allowed to have a compiled binary, but no clearance to compile the code himself

Current feature set

- Laghos (Lagrangian phase of an ALE Shock Hydrodynamics solver) replicated in dFEM with explicit time integration
- Extended implementation to support implicit time integration with automated derivatives from dFEM using Enzyme!

Laghos RK4 CFL 0.5

step 737, $t = 0.8$, $dt = 0.0011935$

Energy difference (initial vs final): $3.60e-05$

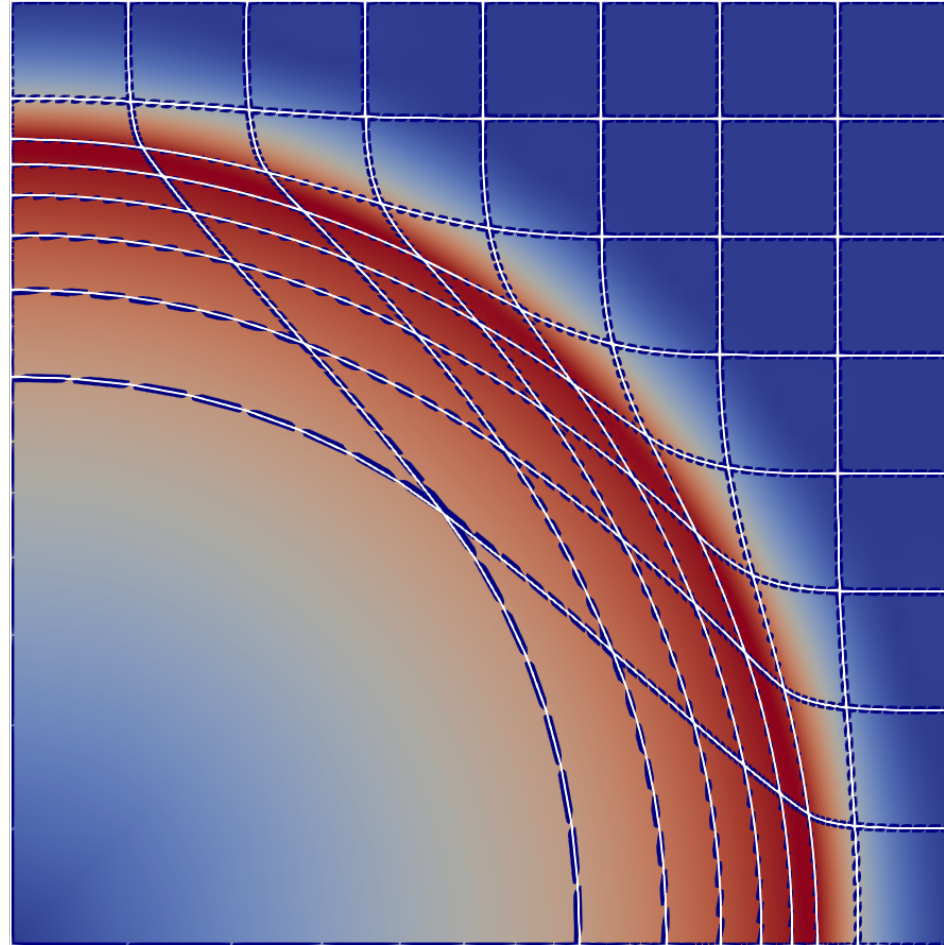

dFEM Implicit Midpoint CFL 5.0

step 101, $t = 0.8$, $dt = 0.00231807$

Energy difference (initial vs final): $5.56e-05$

Comparison of ALE movement from dFEM implicit hydro vs Laghos explicit time integration

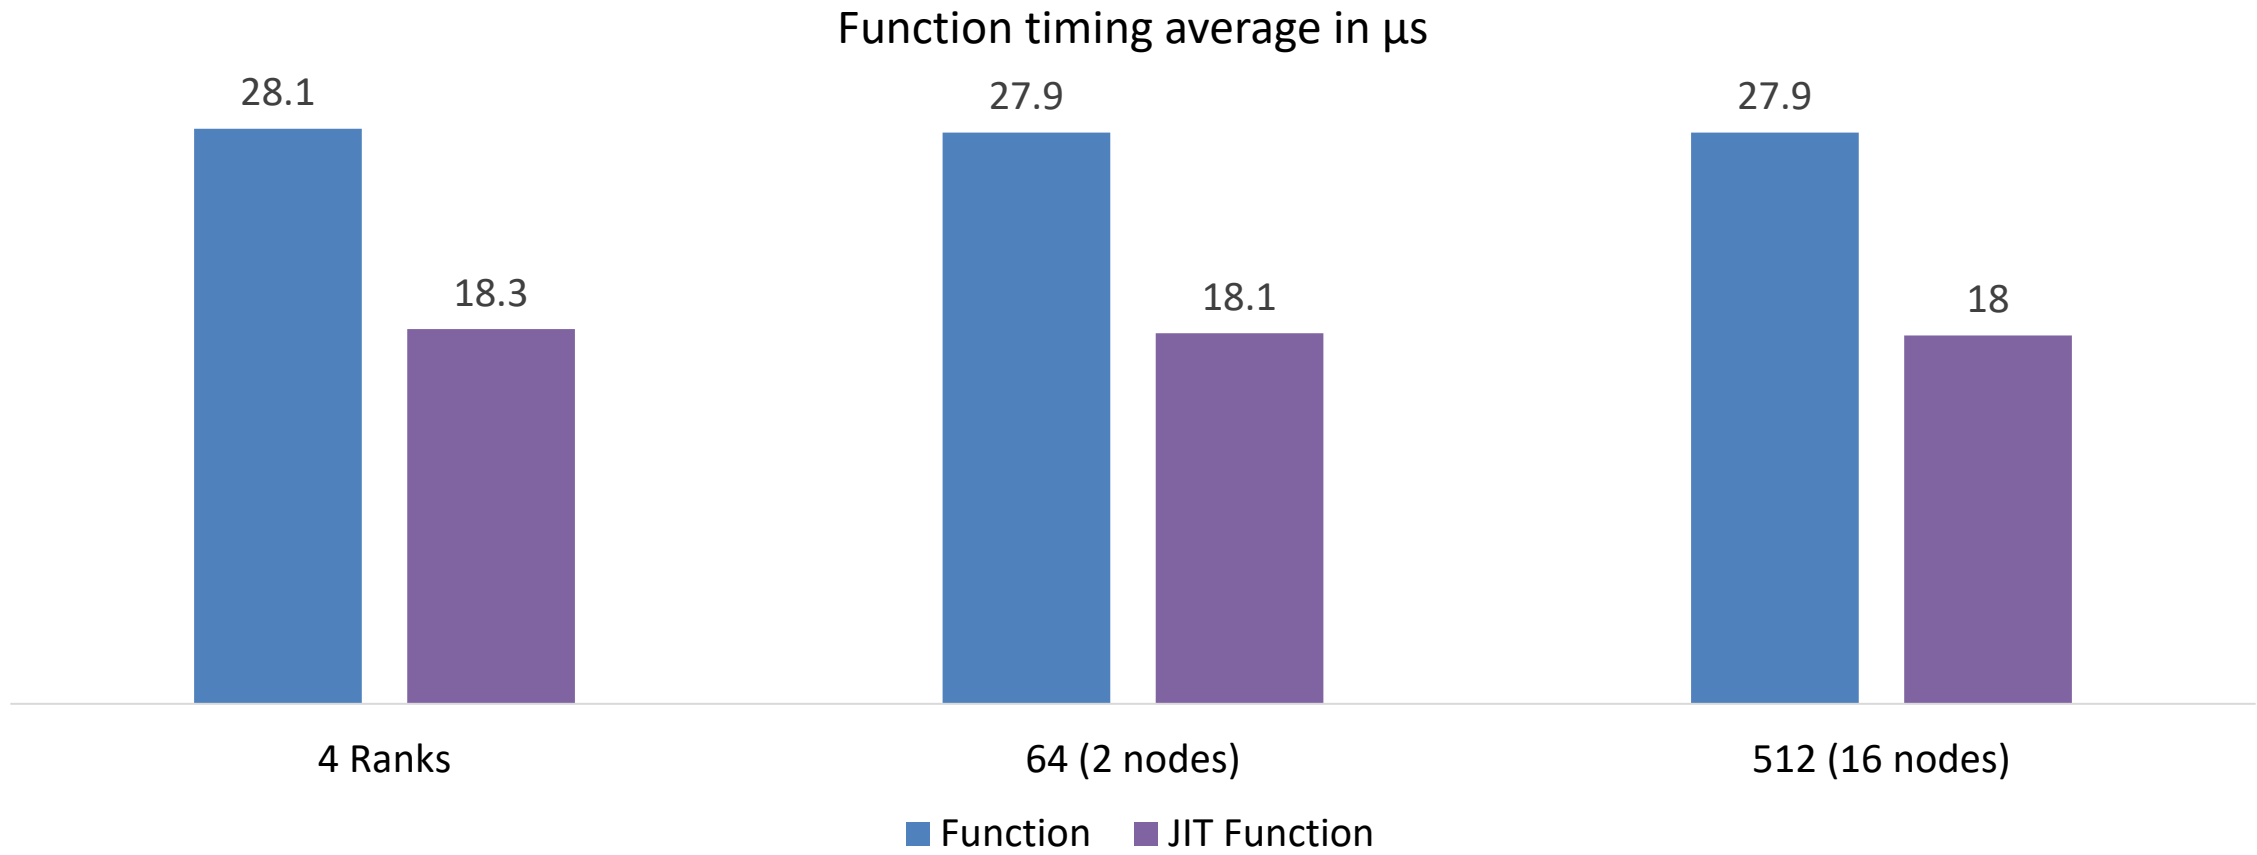

WIP

- Automatic Element Matrix, Processor local Sparse Matrix and global HypreParMatrix assemble
- Automatic Partial Assembly algorithms
 - Takes advantage of derivative knowledge and caches the quadrature point Jacobians as PA data
 - Automatically applies PA data to function
 - Enables no-overhead linearized operator transpose action (👉 Adjoint method)
- JIT (experimental)

Performance. Collab with Giorgis Georgakoudis

- GPU kernel launch latency is 5 μ s

Performance. Collab with Giorgis Georgakoudis

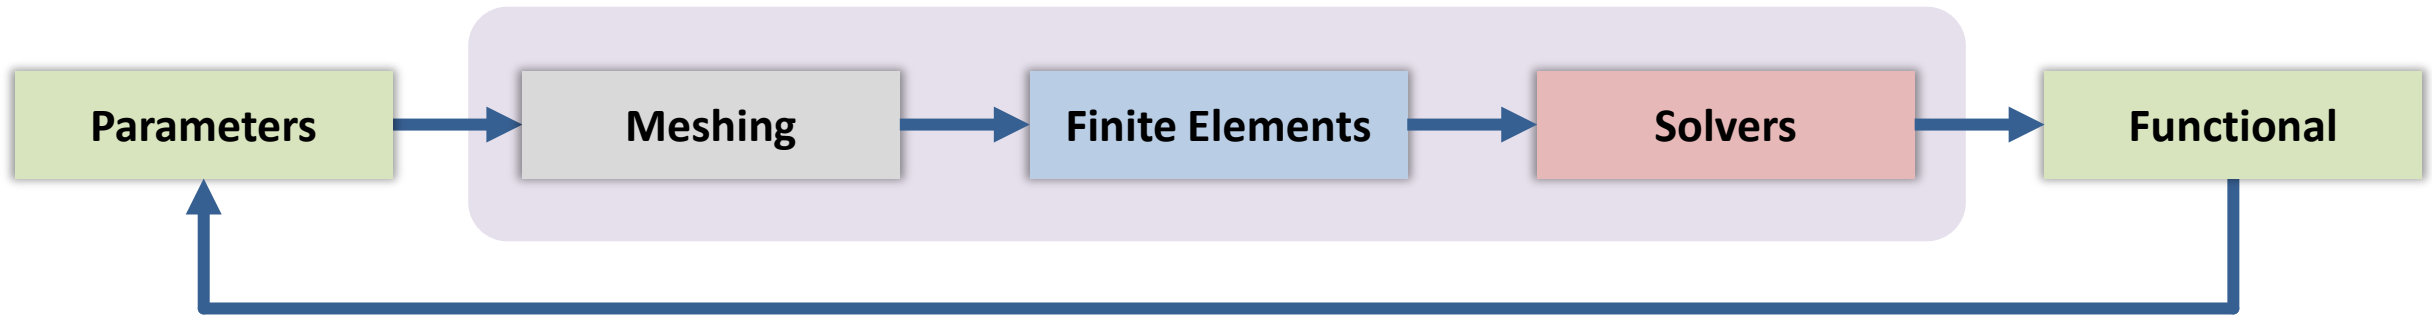

- GPU kernel launch latency is 5 μ s

Derivative timing average in μ s

Automatic Differentiation overview in MFEM

Jacobians and derivatives of FEM operators in a user-friendly way

- FEM decomposition

- Parameters $\hat{\rho} = B_{\rho} G_{\rho} P_{\rho} \rho$
- Parametric nonlinear operator

$$A(u; \rho) = P^T G^T B^T D(\hat{u}, \hat{\rho})$$

- Need to differentiate at **Q-points** only!

$$\nabla_u A(u; \rho) = P^T G^T B^T \nabla_{\hat{u}} D(\hat{u}, \hat{\rho})$$

(Jacobian is FEM decomposed linear operator)

- Differentiate the Q-function D with Enzyme!
 - Can mix code from different languages
 - Differentiate across function calls (e.g., EOS)
 - Many parallel small ADs instead of 1 big one
 - Differentiate only what is necessary
